Topologia algebrica. - Group-like singularities in geometric theories. Nota di Sandro Buoncristiano, presentata (*) dal Corrisp. G. Zappa.

#### Abstract

Riassunto. - In questa Nota si annunciano risultati le cui dimostrazioni verranno pubblicate altrove.

Dato un gruppo abeliano G, si descrive la struttura che occorre introdurre nei (co)-cicli di una teoria di (co)-bordismo $\Omega(-)$ per ottenere $\Omega(-)$ con coefficienti in $G^{\prime \prime}$. Per amore di semplicità ci si concentra sul PL (co)-bordismo, benché la costruzione sia valida in generale.

## Notation

We shall be working in the PL category throughout and will usually omit the prefix PL. Thus, for instance, manifold will stand for PL manifold homeomorphism for PL homeomorphism, etc.

$$
c(X) \equiv \text { cone over } \mathrm{X} ; \quad \text { component } \equiv \text { connected component; }
$$

$|n|=$ absolute value of the integer $n ; \mathrm{Y}^{p}$ denotes an object Y of dimension $p$. If M is a manifold, $\partial \mathrm{M}$ is the set of boundary points of M . If X and V are topological spaces, $\mathrm{X}-\mathrm{Y}$ is the subspace consisting of all the points of X which are not in Y.

Let G be an abelian group, $\theta_{\mathrm{G}}: \mathrm{o} \rightarrow \mathrm{R} \rightarrow \mathrm{F} \rightarrow \mathrm{G} \rightarrow \mathrm{o}$ a free presentation of $G ; R_{0}$ and $F_{0}$ bases in $R$ and $F$ respectively.

Definition i. A $\theta_{\mathrm{G}}$-manifold of dimension $n$ consists of a compact polyhedral pair $\mathrm{M}, \mathrm{SM}$ together with the following structure:
(I) M-SM and SM are oriented manifolds of dimensions $n$ and $n-\mathrm{I}$ respectively.

Convention. We regard the empty set as a manifold of any dimension. Therefore SM may be empty in M.
(2) (Trivialisation). If $V$ is a component of $S M$ there is given a homeomorphism of pairs $h:(\mathrm{N}, \mathrm{V}) \rightarrow(\mathrm{V} \times c(\mathrm{~T}), \mathrm{V})$ where T is a finite set of points and N is a regular neighbourhood of V in M .

Each component of $\mathrm{N}-\mathrm{V}$ will be called a sheet near V .
(3) (Labelling). Each component of $\mathrm{M}-\mathrm{SM}$ is labelled by one element of $F_{0}$ and each component of $S M$ is labelled by one element of $R_{\mathbf{0}}$.

Thus, if V is a component of SM , each of the sheets near V inherits a label and an orientation from M - SM .
(4) (Compatibility). Suppose VCSM is labelled by $r \in \mathrm{R}_{\mathbf{0}}$ with $r=\Sigma n_{g} g, g \in \mathrm{~F}_{0}, n_{g} \in Z$. Then, for each $g$, there are, near V , exactly $\left|n_{g}\right|$ sheets labelled by $g \in \mathrm{~F}_{\mathbf{0}}$. Moreover the orientation of a sheet lebelled by $g$ induces the given orientation on V if and only if $n_{g}>0$.

It is easily checked that the subpolyhedron $\partial \mathrm{M}$ of M given by $\partial \mathrm{M}=$ $=\partial(M-S M) \cup \partial S M$ is a $\theta_{G}$-manifold of dimension $n-I$ with structure (i.e. orientation, labelling, trivialisation) derived from the structure of $M$ by restriction. We call $\partial \mathrm{M}$ the boundary of the $\theta_{\mathrm{G}}$-manifold M .

If M and $\mathrm{M}^{\prime}$ are $\theta_{\mathrm{G}}$-manifolds of dimension $n$, a $\theta_{\mathrm{G}}$-embedding $j: \mathrm{M} \rightarrow \mathrm{M}^{\prime}$ is a PL embedding which preserves the structure.

## Examples

$$
\begin{equation*}
\mathrm{G}=\mathrm{Z} \quad \theta_{\mathrm{Z}}: \mathrm{o} \rightarrow \mathrm{Z} \xrightarrow{\mathrm{id}} \mathrm{Z} \rightarrow 0 \quad \mathrm{~F}_{0}=\{\mathrm{I} \in \mathrm{Z}\} . \tag{I}
\end{equation*}
$$

There are no relations, hence no singularities. A $\theta_{Z}$-manifold is an oriented manifold labelled by $« \mathrm{I} » \in Z$.
(2) $\quad \mathrm{G}=\mathrm{Z}_{n} \quad \theta_{Z_{n}}: \mathrm{o} \rightarrow \mathrm{Z} \xrightarrow{n} \mathrm{Z} \rightarrow \mathrm{Z}_{n} \rightarrow \mathrm{O} \quad \mathrm{R}_{0}=\mathrm{I} \quad \mathrm{F}_{0}=\mathrm{I}$.

The singularities are now of the type $\mathrm{D}^{n-1} \times c\left(\mathrm{~T}_{n}\right)$ where $\mathrm{D}^{n-1}$ is an $(n-\mathrm{I})-$ dimensional disk and $\mathrm{T}_{n}$ is a set of $n$ points. Thus $\theta_{Z_{n}}-$ manifolds are essentially the PL version of Sullivan's smooth $Z_{n}$-manifolds ([3]).
(3) $\mathrm{G}=\mathrm{Z}[\mathrm{I} / 2]$ (= additive group of those rational numbers whose denominators are powers of 2 ), $Z[\mathrm{I} / 2]$ is generated by $\left\{\frac{\mathrm{I}}{2^{i}}: i=0, \mathrm{I}, \cdots\right\}$ with a basic set of relations given by $\left\{r_{j}=\frac{\mathrm{I}}{2^{j}}+\frac{\mathrm{I}}{2^{j}}-\frac{\mathrm{I}}{2^{j-1}}: j=0, \mathrm{I}, \cdots\right\}$.

Germ of a $Z[1 / 2]$ singularity.
Therefore each component $V$ of the singular set is labelled by a relation $r_{j}$ and there are three sheets near V: two of them are labelled by I $/ 2^{j}$ the third is labelled by $\mathrm{I} / 2^{j-1}$ (see picture).

Now let $\mathrm{X}, \mathrm{A}$ be a pair of topological spaces. $A$ singular $\theta_{\mathrm{G}}$-manifold of dimension $n$ is a pair $(M, f)$ consisting of a $\theta_{G}$-manifold $M^{n}$ and a map $f: \mathrm{M}, \partial \mathrm{M} \rightarrow \mathrm{X}, \mathrm{A}$.

Using singular $\theta_{\mathrm{G}}$-manifolds and the notion of $\theta_{\mathrm{G}}$-embedding introduced before, one can define a bordism theory in the standard way (see for example [2]). We write $\Omega_{*}\left(\mathrm{X}, \mathrm{A} ; \theta_{\mathrm{G}}\right)$ for this generalized homology theory.

We have the following theorems.
Theorem i (Universal-Coefficient sequence). For each integer $n \geq 0$ and each pair X, A there exists a short exact sequence:

$$
\mathrm{o} \rightarrow \Omega_{n}(\mathrm{X}, \mathrm{~A}) \otimes \mathrm{G} \rightarrow \Omega_{n}\left(\mathrm{X}, \mathrm{~A} ; \theta_{\mathrm{G}}\right) \rightarrow \operatorname{Tor}\left(\Omega_{n-1}(\mathrm{X}, \mathrm{~A}), \mathrm{G}\right) \rightarrow \mathrm{o}
$$

which is natural in $\mathrm{X}, \mathrm{A}$
ThEOREM 2. Up to equivalence of homology theories $\Omega_{*}\left(\mathrm{X}, \mathrm{A} ; \theta_{\mathrm{G}}\right)$ does not depend on any of the following choices
(a) the presentation $\theta_{G}$ of G ;
(b) the bases $\mathrm{R}_{0}$ and $\mathrm{F}_{0}$.

Then, for each abelian group $G$, fix a presentation $\theta_{G}$ and define $\Omega_{*}(\mathrm{X}, \mathrm{A} ; \mathrm{G})$, PL oriented bordism with coefficients G , by $\Omega_{*}(\mathrm{X}, \mathrm{A} ; \mathrm{G})=$ $=\Omega_{*}\left(\mathrm{X}, \mathrm{A} ; \theta_{\mathrm{G}}\right)$.

Theorem 3. The homology theory $\Omega_{*}(\mathrm{X}, \mathrm{A} ; \mathrm{G})$ is functorial on the category of abelian groups.

Corollary. The Universal-coefficient sequence of Theorem I is natural on the category of abelian groups.

Theorem 4 (The Bockstein sequence). On the category of short exact sequences of abelian groups

$$
\mathrm{o} \rightarrow \mathrm{G}^{\prime} \xrightarrow{\psi} \mathrm{G} \xrightarrow{\varphi} \mathrm{G}^{\prime \prime} \rightarrow \mathrm{o}
$$

there is a natural connecting homomorphism

$$
\beta: \Omega_{n}\left(\mathrm{X}, \mathrm{~A} ; \mathrm{G}^{\prime \prime}\right) \rightarrow \Omega_{n-1}\left(\mathrm{X} ; \mathrm{A} ; \mathrm{G}^{\prime}\right)
$$

of degree - I and a natural long exact sequence

$$
\cdots \rightarrow \Omega_{n}\left(\mathrm{X}, \mathrm{~A} ; \mathrm{G}^{\prime}\right) \xrightarrow{\psi_{*}} \Omega_{n}(\mathrm{X}, \mathrm{~A} ; \mathrm{G}) \xrightarrow{\varphi_{*}} \Omega_{n}\left(\mathrm{X}, \mathrm{~A} ; \mathrm{G}^{\prime \prime}\right) \rightarrow \cdots
$$

The proofs of the above theorems are entirely geometric in nature.
We now turn briefly to cobordism. In order to put coefficients $G$ in cobordism we use the geometric description of cobordism given in [r]. Let $K$ be an oriented cell complex, i.e. one in which each cell is oriented. Let G be an abelian group and $\theta_{\mathrm{G}}$ a presentation of G .

Definition 2. A $\left(\theta_{\mathrm{G}}, q\right)$-mock bundle $\xi^{q} / \mathrm{K}$, with base K and total space E , is a projection $p: \mathrm{E} \rightarrow|\mathrm{K}|$ such that:
(a) for each $\sigma \in \mathrm{K}, p^{-1}(\sigma)$ is the interior of a $\theta_{\mathrm{G}}$-manifold $\xi_{\sigma}$ whose dimension equals $q+\operatorname{dim} \sigma$.
(b) for each $\sigma \in \mathrm{K}, \xi_{\sigma}=\bigcup_{\tau \leqq \sigma}[\tau: \sigma] p^{-1}(\tau)$ where $[\tau: \sigma]$ is the incidence number of $\tau$ and $\sigma$.
(Here, if M is a $\theta_{\mathrm{G}}$-manifold, -M stands for the $\theta_{\mathrm{G}}$-manifold obtained from M by reversing all the orientations).

Using $\theta_{\mathrm{G}}$-mock bundles as in [I], a generalized cohomology theory $\Omega^{*}(|\mathrm{~K}|, \mathrm{G})$ is obtained and the cohomological versions of Theorems i to 4 can be proved.
