Geometria. - Some remarks about the contact of hypersurfaces along multiple subvarieties. Nota di Mauro Beltrametti, presentata ${ }^{(*)}$ dal Socio E. G. Togliatti.

#### Abstract

RiAsSunto. - Estendendo ricerche di D. Gallarati [2] e di molti altri Autori sul contatto tra due ipersuperficie d'uno spazio proiettivo $S_{r}$ lungo una varietà ad $r-2$ dimensioni, si considera il caso in cui il contatto avvenga lungo le varie falde d'una varietà multipla per le due ipersuperficie.

I. First, we mention some definitions and known results to be used in the sequel (see also [3], par. 8).

Let us denote by $\left(\mathrm{X}, \mathrm{O}_{\mathrm{X}}\right),\left(\mathrm{Y}, \mathrm{O}_{\mathrm{Y}}\right)$ two algebraic varieties defined on a field $k$, by $\mathfrak{d}$ a sheaf of ideals of $\mathrm{O}_{\mathrm{X}}$, by $f: \mathrm{Y} \rightarrow \mathrm{X}$ a morphism and by $f^{*}: \mathrm{O}_{\mathrm{X}} \rightarrow \mathrm{O}_{\mathrm{Y}}$ the associated morphism between the structure sheaves.

Definition (i). We say that $f$ makes the ideal $\mathfrak{J}$ invertible (or divisorial) if $f^{-1} \mathfrak{I}$ is an invertible sheaf on Y , where $f^{-1} \mathfrak{g}$ is the ideal generated by the image of $f^{*} \mathfrak{J}$ in $\mathrm{O}_{\mathrm{Y}}$.

Definition (2). Denoting by $\sigma: \mathrm{X}^{\prime} \rightarrow \mathrm{X}$ a morphism which makes $\mathfrak{d}$ invertible, the pair $\left(\mathrm{X}^{\prime}, \sigma\right)$ is said to be a blow up of X along $\mathfrak{y}$ if for every morphism $f: \mathrm{Y} \rightarrow \mathrm{X}$, which makes $\mathfrak{d}$ invertible, there exists one and only one morphism $\tau: \mathrm{Y} \rightarrow \mathrm{X}^{\prime}$ such that the diagram:

commutes.

Proposition (i). Let X be a variety and $\mathfrak{I}$ a sheaf of ideals of $\mathrm{O}_{\mathrm{x}}, \mathfrak{I} \neq \mathrm{o}$. Then there exists a blow up $\left(\mathrm{X}^{\prime}, \sigma\right)$ of X along $\mathfrak{d}$ which is unique up to isomorphisms.

Definition (3). Let $Z$ be a closed subset of $X$ defined by the ideal $\mathfrak{I}_{Z}$ of $\mathrm{O}_{\mathrm{x}}$. The blow up of X along $\mathfrak{I}_{\mathrm{Z}}$ is called blow up of X along $Z$. In particular if $Z$ is a point $P$ we get blow up of $X$ at $P$.

Proposition (2). If X and Z are non singular $\mathrm{X}^{\prime}$ is non singular, moreover $\operatorname{dim} \mathrm{X}=\operatorname{dim} \mathrm{X}^{\prime}$.

Last, we observe that if $\left(\mathrm{X}^{\prime}, \sigma\right)$ is the blow up of X along $\mathfrak{I}$ and if U is a nonempty open set of X , then $\left(\sigma^{-1}(\mathrm{U}), \sigma / \sigma^{-1}(\mathrm{U})\right)$ is the blow up of $(\mathrm{U}, \mathscr{I} / \mathrm{U})$.
(*) Nella seduta del 12 maggio 1973.

Let X be a non singular, irreducible, complete algebraic variety of dimension $n$, defined over an algebraically closed field $k$ of characteristic zero, let D be an hypersurface of $\mathrm{X}, \mathrm{V}$ a non singular, irreducible, subvariety of X of codimension $\lambda+\mathrm{I}$. $\mathscr{J}_{\nu}$ the sheaf of ideals of $\mathrm{O}_{\mathrm{x}}$ defining $V$. Further, we denote by P a point of V , by U an affine neighborhood of P in X , by $f=0$, with $f \in \Gamma\left(\mathrm{U}, \mathrm{O}_{\mathrm{x}}\right)$, a local equation of D in U and write $\mathfrak{\mathscr { R }}_{v}=\Gamma\left(\mathrm{U}, \mathfrak{I}_{v}\right)$. We set the following:

Definition (4). D passes through V with multiplicity $s$ if:

$$
f \in \mathfrak{Q}_{v}^{s} \quad, \quad f \notin \mathscr{O}_{v}^{s+1}
$$

Let us now assume that D passes through V with multiplicity $s$ and that there exists an effective divisor $\Delta$ of V such that the generic point of every irreducible component $\delta$ of $\Delta$ has multiplicity $s_{1}{ }^{(1)}$ with respect to $\mathrm{D}\left(s_{1}>s\right)$. Thus if $\mathscr{J}_{\delta}$ is the sheaf of ideals defining $\delta$ and $\mathfrak{T}_{\delta}=\Gamma\left(\mathrm{U}, \mathfrak{J}_{\delta}\right)$ we have:

$$
\begin{equation*}
f \in \mathscr{O}_{v}^{s} \quad, \quad f \notin \mathscr{Q}_{v}^{s+1} \quad ; \quad f \in \mathscr{Q}_{\delta}^{s_{1}} \quad, \quad f \notin \mathscr{O}_{\delta}^{s_{1}^{1}+1} . \tag{I}
\end{equation*}
$$

By the hypothesis made, it is possible to choose the affine neighborhood $U$ such that V and $\delta$ become complete intersection on U ; hence we get:

$$
\mathfrak{Q}_{v}=\left(g_{1}, \cdots, g_{\lambda+1}\right) \quad, \quad \mathscr{N}_{\delta}=\left(g_{1}, \cdots, g_{\lambda+2}\right) \quad, \quad g_{i} \in \Gamma\left(\mathrm{U}, \mathrm{O}_{\mathrm{x}}\right)
$$

Let $\left(\sigma^{-1}(\mathrm{U}), \sigma / \sigma^{-1}(\mathrm{U})\right)$ be the blow up of U along $\mathrm{V} \cap \mathrm{U}$, induced by the blow up $\left(X^{\prime}, \sigma\right)$ of $X$ along $V$. In the variety $U \times \mathbf{P}^{\lambda}$ we consider the closed subset $U^{\prime}$ defined by the equations:

$$
g_{i} \mathrm{X}_{j}-g_{j} \mathrm{X}_{i}=\mathrm{o} \quad i, j=\mathrm{I}, \cdots, \lambda+\mathrm{I}
$$

where $\mathrm{X}_{1}, \cdots, \mathrm{X}_{\lambda+1}$ are homogeneous coordinates in $\mathbf{P}^{\lambda}$. Outside of V the projection $\sigma: \mathrm{U}^{\prime} \rightarrow \mathrm{U}$ is an isomorphism and $\mathrm{U}^{\prime}=\sigma^{-1}(\mathrm{U})$.

Now we prove that $\mathscr{I}_{v}$ becomes divisorial on $U^{\prime}$. To achieve this purpose take over $\mathrm{U} \times \mathbf{P}^{\lambda}$ the open set $\mathrm{U} \times \mathrm{U}_{i}$, with $\mathrm{U}_{i}=\operatorname{Spec}\left(k\left[\frac{\mathrm{X}_{1}}{\mathrm{X}_{i}}, \cdots, \frac{\mathrm{X}_{\lambda+1}}{\mathrm{X}_{i}}\right]\right)$. $\mathrm{U}^{\prime}$ is defined on $\mathrm{U} \times \mathrm{U}_{i}$ by the equations: $g_{j}=g_{i} \frac{\mathrm{X}_{j}}{\mathrm{X}_{i}}, j=\mathrm{I}, \cdots, \lambda+\mathrm{I}$ ( $i$ fixed); hence on $\mathrm{U}^{\prime} \cap\left(\mathrm{U} \times \mathrm{U}_{i}\right)$ the ideal $\sigma^{-1} \mathfrak{I}_{\nu}$ is generated by $g_{i}$. Thus $g_{i}$ defines on $\mathrm{U}^{\prime} \cap\left(\mathrm{U} \times \mathrm{U}_{i}\right)$ the exceptional divisor $\mathrm{E}=\sigma^{-1}(\mathrm{~V})$. One gets:

$$
\mathrm{U} \times \mathrm{U}_{i}=\operatorname{Spec}\left(\Gamma\left(\mathrm{U}, \mathrm{O}_{\mathrm{x}}\right)\left[\frac{\mathrm{X}_{1}}{\mathrm{X}_{i}}, \cdots, \frac{\mathrm{X}_{\lambda+1}}{\mathrm{X}_{i}}\right]\right)
$$

so that:

$$
\mathrm{U}^{\prime} \cap\left(\mathrm{U} \times \mathrm{U}_{i}\right)=\operatorname{Spec}\left(\Gamma\left(\mathrm{U}, \mathrm{O}_{\mathrm{X}}\right)\left[\frac{\mathrm{X}_{1}}{\mathrm{X}_{i}}, \cdots, \frac{\mathrm{X}_{\lambda+1}}{\mathrm{X}_{i}}\right] /\left(\cdots, g_{j}-g_{i} \frac{\mathrm{X}_{j}}{\mathrm{X}_{i}}, \cdots\right)\right)
$$

Putting $\mathrm{U}_{g_{i}}=\mathrm{U}-\left\{g_{i}=0\right\}$ it follows:

$$
\mathrm{U}_{i}^{\prime}:=\mathrm{U}^{\prime} \cap\left(\mathrm{U}_{g_{i}} \times \mathrm{U}_{i}\right)=\operatorname{Spec}\left(\Gamma\left(\mathrm{U}, \mathrm{O}_{\mathrm{x}}\right)\left[\frac{g_{1}}{g_{i}}, \cdots, \frac{g_{\lambda+1}}{g_{i}}\right]\right)
$$

(I) Shortly denoted, in the sequel, by $s_{1}$-point.
2. Let $f=\mathrm{o}$ be a local equation of D in U ; owing to the relations ( I ) there exist $\alpha_{s}, \alpha_{s+1}, \cdots, \alpha_{s_{1}}$ with $\alpha_{j} \in \mathscr{V}_{v}^{j}\left(j=s, \cdots, s_{1}\right), \alpha_{s} \notin \mathscr{Q}_{v}^{s+1}$ and $\alpha_{s}$ homogeneous such that:

$$
\begin{equation*}
f-\left(g_{\lambda+2}^{s_{1}-s} \alpha_{s}+g_{\lambda+2}^{s_{1}-s-1} \alpha_{s+1}+\cdots+g_{\lambda+2} \alpha_{s_{1}-1}+\alpha_{s_{1}}\right) \in \mathscr{V}_{\nu}^{s_{1}+1} \tag{2}
\end{equation*}
$$

On the open set $\mathrm{U}_{g_{i}}$ write $g_{k}=g_{i} \frac{g_{k}}{g_{i}}(k=\mathrm{I}, \cdots, \lambda+2)$ : since $\alpha_{j} \in \mathscr{\Upsilon}_{v}^{j}$ we get, for every $j, \alpha_{j}=g_{i}^{j} \beta_{j}$, where

$$
\beta_{j} \in\left(\frac{g_{1}}{g_{i}}, \cdots, \frac{g_{\lambda+1}}{g_{i}}\right)^{j} \Gamma\left(\mathrm{U}, \mathrm{O}_{\mathrm{x}}\right) .
$$

Hence in $\mathrm{U}_{g_{i}}$ a relation of the form:

$$
\begin{equation*}
f=g_{i}^{s}\left[g_{\lambda+2}^{s_{1}-s} \beta_{s}+g_{i} \cdot \eta\right]=0 \tag{3}
\end{equation*}
$$

holds, where $g_{i}$ does not divide $\beta_{s}$ and where $\eta$ is element of $\mathfrak{V}_{v}^{s_{1}}$.
In the open set $\mathrm{U}_{i}^{\prime}$ we have the following: $g_{i}=0$ is an equation of the exceptional divisor $\mathrm{E}, g_{\lambda+2}^{s_{1}-s} \cdot \beta_{s}+g_{i} \cdot \eta$ stands for the proper transform $\mathrm{D}^{(1)}$ of $\mathrm{D}, g_{\lambda+2}=\mathrm{o}$ is an equation of $\delta^{*}=\sigma^{-1}(\delta) \in \operatorname{Div}(\mathrm{E})$. Moreover, if $\mathrm{V}_{1}$ is the divisor of E locally represented by the equation $\beta_{s}=0{ }^{(2)}$, we get on E:

$$
\mathrm{E} \cdot \mathrm{D}^{(1)}=\mathrm{V}_{1}+\left(s_{1}-s\right) \delta^{*}
$$

(taking into account that the open sets $\mathrm{U}_{i}^{\prime}$ are a covering of $\mathrm{U}^{\prime}$ ).
Therefore, we have proved the following
Proposition (3). $\mathrm{O}_{\mathrm{X}^{\prime}}\left(\mathrm{D}^{(1)}\right) \otimes_{\mathrm{O}_{\mathrm{X}^{\prime}}} \mathrm{O}_{\mathrm{E}}=\mathrm{O}_{\mathrm{E}}\left(\mathrm{V}_{1}\right) \otimes_{\mathrm{o}_{\mathrm{X}^{\prime}}} \mathrm{O}_{\mathrm{E}}\left(\left(s_{1}-s\right) \delta^{*}\right)$.
Remark: $\left(g_{1}, \cdots, g_{\lambda+1}\right)$ is a $\Gamma\left(\mathrm{U}, \mathrm{O}_{\mathrm{x}}\right)$ sequence and, if $\mathrm{P} \notin \Delta$, it may be completed in $\mathrm{O}_{\mathrm{X}, \mathrm{P}}$ to a $\mathrm{O}_{\mathrm{X}, \mathrm{P}}$ sequence ( $g_{1}^{\prime}, \cdots, g_{\lambda+1}^{\prime}, \cdots, g_{n}^{\prime}$ ) formed by a regular system of parameters, where $g_{i}^{\prime}$ is the image of $g_{i}$ in $\mathrm{O}_{\mathrm{X}, \mathrm{P}}, i=\mathrm{I}, \cdots, \lambda+\mathrm{I}$. Hence $g_{\alpha}^{\prime}, \alpha=\mathrm{I}, \cdots, n$ may be viewed as indeterminates [ I ].
3. Let $\mathrm{D}_{1}, \mathrm{D}_{2}$ be two hypersurfaces of X passing with multiplicity $s$ through the subvariety V of X . Hereinafter we shall assume that an open set $U_{V}$ of $V$ exists in which $D_{1}$ and $D_{2}$ have $s$ distinct branches: we mean that for every point $P$ of $U_{V}$ it is possible to find a surface intersecting $D_{1}$ and $D_{2}$ in two curves, each having at $\mathrm{P} s$ distinct tangent lines (i.e. P is an ordinary $s$-point for the two section curves). Moreover, we assume the existence of two divisors $\delta_{1}$ and $\delta_{2}$ of $\mathrm{V}, \operatorname{loci}{ }^{(3)}$ of $s_{1}$ and $s_{2}$-points for $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ respectively $\left(s_{1}>s, s_{2}>s\right)$.
(2) Clearly $V_{1}$ does not depend on the choice of $\alpha_{s}$.
(3) (i.e. the generic point of every irreducible component of $\delta_{i}$ is $s_{i}$-point, $i=1,2$ ).

If in the affine open set U the divisor $\mathrm{D}_{i}$ has equation $f_{i}=\mathrm{o}(i=\mathrm{I}, 2)$, we write, with the notation of the previous section:

$$
\begin{align*}
& f_{1}=g_{i}^{s}\left[g_{\lambda+2}^{s_{1}-s} \beta_{s}^{(1)}+g_{i} \cdot \eta_{1}\right]=0  \tag{4}\\
& f_{2}=g_{i}^{s}\left[g_{\lambda+2}^{s_{2}-s} \beta_{s}^{(2)}+g_{i} \cdot \eta_{2}\right]=0 .
\end{align*}
$$

If the divisors $V_{1}, V_{2}$ of $E$, locally represented on $U_{i}^{\prime}$ by $\beta_{s}^{(1)}=0$, $\beta_{s}^{(2)}=0$, coincide then $\alpha_{s}^{(1)}=g_{i}^{s} \beta_{s}^{(1)}$ and $\alpha_{s}^{(2)}=g_{i}^{s} \beta_{s}^{(2)}$ coincide up to invertible factors. This means that in every point $\mathrm{P} \in \mathrm{V}$ not belonging to Supp $\delta_{1} \cup \operatorname{Supp} \delta_{2}, \mathrm{D}_{1}$ and $\mathrm{D}_{2}$ have the same tangent cone. In fact, on account of remark of Section 2 we get, for every such point $P$ :

$$
\widehat{\mathrm{O}}_{\mathrm{x}, \mathrm{P}} \stackrel{\stackrel{\xi}{\simeq}}{\simeq} k \llbracket g_{1}^{\prime}, \cdots, g_{n}^{\prime} \| .
$$

On the other hand the tangent cone to $D_{1}$ at $P$ is the affine scheme:

$$
\begin{aligned}
& \operatorname{Spec}\left(g r \mathrm{O}_{\mathrm{D}_{1}, \mathrm{P}}\right)=\operatorname{Spec}\left(g r \mathrm{O}_{\mathrm{x}, \mathrm{P}} /\left(f_{1}\right) \mathrm{O}_{\mathrm{x}, \mathrm{P}}\right) \simeq \\
\simeq & \operatorname{Spec}\left(g r \widehat{\mathrm{O}}_{\mathrm{x}, \mathrm{P}} /\left(f_{1}\right) \widehat{\mathrm{O}}_{\mathrm{X}, \mathrm{P}}\right) \simeq \operatorname{Spec}\left(\operatorname{gr} k \llbracket g_{1}^{\prime}, \cdots, g_{n}^{\prime} \| /\left(\xi\left(f_{1}\right)\right)\right) \simeq \\
\simeq & \operatorname{Spec}\left(g r k\left\|g_{1}^{\prime}, \cdots, g_{n}^{\prime}\right\| /\left(\bar{\xi}\left(f_{1}\right)\right)\right),
\end{aligned}
$$

where $\overline{\xi\left(f_{1}\right)}$ is the lower-degree term of $\xi\left(f_{1}\right)$; since $\alpha_{s}^{(1)}, \alpha_{s}^{(2)}$ are homogeneous: $\overline{\xi\left(f_{1}\right)}=\rho \overline{\xi\left(f_{2}\right)}, \rho \in k$, is equivalent to $\mathrm{V}_{1}=\mathrm{V}_{2}$.
4. We denote $D_{1}^{(1)}$ and $D_{2}^{(1)}$ the proper transforms of the divisors $D_{1}$ and $\mathrm{D}_{2}$ while $\delta_{1}^{*}$ and $\delta_{2}^{*}$ stand for the inverse images of $\delta_{1}$ and $\delta_{2}\left(\delta_{i} \in \operatorname{Div}(\mathrm{~V})\right.$, $i=\mathrm{I}, 2$ ).

Formulas (4) yield:

$$
\mathrm{O}_{\mathrm{X}^{\prime}}\left(\mathrm{D}_{1}^{(1)}\right) \otimes \mathrm{o}_{\mathrm{X}^{\prime}} \mathrm{O}_{\mathrm{E}}=\mathrm{O}_{\mathrm{E}}\left(\mathrm{~V}_{1}+\left(s_{1}-s\right) \delta_{1}^{*}\right)
$$

and

$$
\mathrm{O}_{\mathrm{X}^{\prime}}\left(\mathrm{D}_{2}^{(1)}\right) \otimes \mathrm{o}_{\mathrm{X}^{\prime}} \mathrm{O}_{\mathrm{E}}=\mathrm{O}_{\mathrm{E}}\left(\mathrm{~V}_{2}+\left(s_{2}-s\right) \delta_{2}^{*}\right)
$$

Whenever $D_{1}$ and $D_{2}$ have the same tangent cone at the points of $V$ not belonging to $\operatorname{Supp} \delta_{1} \cup \operatorname{Supp} \delta_{2}$, i.e. in the hypothesis $V_{1}=V_{2}$, one has:

$$
\mathrm{O}_{\mathrm{X}^{\prime}}\left(\mathrm{D}_{1}^{(1)}-\mathrm{D}_{2}^{(1)}\right) \otimes_{\mathrm{o}^{\prime}} \mathrm{O}_{\mathrm{E}}=\mathrm{O}_{\mathrm{E}}\left[\left(s_{1}-s\right) \delta_{1}^{*}-\left(s_{2}-s\right) \delta_{2}^{*}\right] .
$$

Suppose $\mathrm{V}_{1}$ be a prime, non singular divisor (this is motivated by the generality of $\left.\alpha_{s}^{(1)}\right)^{(4)}$.
(4) The argument which follows can be extended, with minor changes, to the case where $\mathrm{V}_{1}$ is reducible with every component non singular, by considering every irreducible component.

Tensoring by $\mathrm{O}_{\mathrm{V}_{1}}=\mathrm{O}_{\mathrm{V}_{2}}$ on $\mathrm{O}_{\mathrm{E}}$ and still denoting by $\delta_{i}^{*}$ the divisors intersected on $\mathrm{V}_{1}$ by $\delta_{i}^{*}, i=\mathrm{I}, 2$ :

$$
\begin{equation*}
\mathrm{O}_{\mathrm{x}^{\prime}}\left(\mathrm{D}_{1}^{(1)}-\mathrm{D}_{2}^{(1)}\right) \otimes \otimes_{\mathrm{o}^{\prime}} \mathrm{O}_{\mathrm{V}_{1}}=\mathrm{O}_{\mathrm{V}_{1}}\left[\left(s_{1}-s\right) \delta_{1}^{*}-\left(s_{2}-s\right) \delta_{2}^{*}\right] . \tag{5}
\end{equation*}
$$

Let now $\overline{\mathrm{D}}_{1}$ and $\overline{\mathrm{D}}_{2}$ be two divisors of X such that $\overline{\mathrm{D}}_{1} \equiv \mathrm{D}_{1}, \overline{\mathrm{D}}_{2} \equiv \mathrm{D}_{2}$ and assume that $\bar{D}_{1}, \bar{D}_{2}$ do not contain $V$ ([5], Cap. II, par. 3). Putting $\overline{\mathrm{D}}_{i}^{*}=\sigma^{-1}\left(\overline{\mathrm{D}}_{i}\right), i=\mathrm{I}, 2$, it follows:

$$
\overline{\mathrm{D}}_{1}^{*}-\overline{\mathrm{D}}_{2}^{*} \equiv \mathrm{D}_{1}^{(1)}+s \mathrm{E}-\mathrm{D}_{2}^{(1)}-s \mathrm{E}=\mathrm{D}_{1}^{(1)}-\mathrm{D}_{2}^{(1)} ;
$$

whence, by use of (5):

$$
\begin{equation*}
\mathrm{O}_{\mathrm{X}^{\prime}}\left(\overline{\mathrm{D}}_{1}^{*}-\overline{\mathrm{D}}_{2}^{*}\right) \otimes_{\mathrm{o}_{\mathrm{X}^{\prime}}} \mathrm{O}_{\mathrm{v}_{1}}=\mathrm{O}_{\mathrm{v}_{1}}\left[\left(s_{1}-s\right) \delta_{1}^{*}-\left(s_{2}-s\right) \delta_{2}^{*}\right] . \tag{6}
\end{equation*}
$$

This formula is equivalent to state the linear equivalence of the two divisors intersected on $\mathrm{V}_{1}$ by $\left(s_{1}-s\right) \delta_{1}^{*}-\left(s_{2}-s\right) \delta_{2}^{*}$ and by $\bar{D}_{1}^{*}-\bar{D}_{2}^{*}$ respectively.

We remark that, if $\left(s_{1}-s\right) \delta_{1}^{*}-\left(s_{2}-s\right) \delta_{2}^{*} \equiv \mathrm{o}$, in particular if $\delta_{1}=\delta_{2}=0$, whe have:

$$
\mathrm{O}_{\mathrm{E}}\left[\left(\overline{\mathrm{D}}_{1}^{*}-\overline{\mathrm{D}}_{2}^{*}\right) \cdot \mathrm{E}\right]=\mathrm{O}_{\mathrm{E}}
$$

then, since $\sigma_{*} \mathrm{O}_{\mathrm{E}}=\mathrm{O}_{\mathrm{V}}$ :

$$
\begin{equation*}
\left(\overline{\mathrm{D}}_{1}-\overline{\mathrm{D}}_{2}\right) \cdot \mathrm{V} \equiv \mathrm{o} . \tag{7}
\end{equation*}
$$

We suppose now that the subvariety V has codimension two $(\lambda=\mathrm{I})$. In this case there exists on $V$ an open set $U_{V}$ such that the restriction to $U_{V}$ of the morphism $\tau=\sigma / \mathrm{V}_{1}: \mathrm{V}_{1} \rightarrow \mathrm{~V}$ has finite fibres ([4], Cap. I, p. 96), all of them being formed by $s$ distinct points. Indeed if $\mathrm{U}_{\mathrm{V}}$ is the open set of V in which $D_{1}$ and $D_{2}$ have $s$ distinct branches and if $S$ is a surface which intersects $V$ in a point P and $\mathrm{D}_{1}, \mathrm{D}_{2}$ along curves having in P an ordinary $s$-point, the blow up of X along V induces blow up at P of both these curves; furthermore P blows up in $s$ distinct points belonging to $\mathrm{V}_{1}$.

In the hypothesis that the variety X has dimension 3 and that all the points forming the divisor $\delta_{i}(i=\mathrm{I}, 2)$ have the same multiplicity $s_{i}=s+\mathrm{I}$ (this situation is a general one) eq. (6) implies that the two divisors intersected on the curve $V_{1}$ by $\delta_{1}^{*}-\delta_{2}^{*}$ and by $\bar{D}_{1}^{*}-\bar{D}_{2}^{*}$ have the same degree. Since the divisors $\overline{\mathrm{D}}_{1}$ and $\overline{\mathrm{D}}_{2}$ may be choosen to ensure that no point $\mathrm{P} \notin \mathrm{U}_{\mathrm{V}}$ is contained in Supp $\overline{\mathrm{D}}_{1} \cup \operatorname{Supp} \overline{\mathrm{D}}_{2}$, we have:

$$
\begin{equation*}
\operatorname{deg}\left(\overline{\mathrm{D}}_{1}^{*}-\overline{\mathrm{D}}_{2}^{*}\right)_{/ \mathrm{v}_{1}}=s \operatorname{deg}\left(\overline{\mathrm{D}}_{1}-\overline{\mathrm{D}}_{2}\right)_{/ \mathrm{v}} \tag{8}
\end{equation*}
$$

then:

$$
s \operatorname{deg}\left(\overline{\mathrm{D}}_{1}-\overline{\mathrm{D}}_{2}\right)_{/ \mathrm{v}}=\operatorname{deg} \delta_{1}^{*}-\operatorname{deg} \delta_{2}^{*} .
$$

On the other hand ${ }^{(5)}$ :

$$
\operatorname{deg} \delta_{1}^{*}=s \operatorname{deg} \delta_{1} \quad, \quad \operatorname{deg} \delta_{2}^{*}=s \operatorname{deg} \delta_{2}
$$

whence:

$$
\begin{equation*}
\operatorname{deg}\left(\bar{D}_{1}-\overline{\mathrm{D}}_{2}\right)_{/ \mathrm{V}}=\operatorname{deg} \delta_{1}-\operatorname{deg} \delta_{2} \tag{9}
\end{equation*}
$$

Let us make the following remark: if $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ are two surfaces, of orders $d_{1}$ and $d_{2}$, belonging to $\mathrm{X}=\mathbf{P}^{3}$ and if $h$ is the order of the curve V , we have from (9):

$$
h\left(\mathrm{~d}_{1}-\mathrm{d}_{2}\right)=\operatorname{deg} \delta_{1}-\operatorname{deg} \delta_{2} .
$$

If $\delta_{1} \equiv \delta_{2}$ (in particular if $\delta_{1}=\delta_{2}=0$ ) it follows $\mathrm{d}_{1}=\mathrm{d}_{2}$. Thus we have proved the following:

Proposition (4). Let $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$ be two algebraic surfaces of $\mathbf{P}^{3}$, each passing with multiplicity $s$, and with $s$ distinct branches, through a non singular curve $V$ of order $h$. If $\delta_{i}$ is the divisor on V locus of $s_{i}$-points $\left(s_{i}=\mathrm{I}+s\right)$ for $\mathrm{D}_{i}(i=\mathrm{I}, 2)$ and if $\mathrm{D}_{1}, \mathrm{D}_{2}$ have the same tangent cone at the points of V not belonging to Supp $\delta_{1} \cup$ Supp $\delta_{2}$, then the equality $h\left(\mathrm{~d}_{1}-\mathrm{d}_{2}\right)=$ $=\operatorname{deg} \delta_{1}-\operatorname{deg} \delta_{2}$ holds .

Corollary. Two surfaces $\mathrm{D}_{1}, \mathrm{D}_{2}$ of $\mathbf{P}^{3}$ both passing with multiplicity s through a non singular curve C and not having on C points of multiplicity $>s$, can have the same tangent cone along C only if their orders are equal.

The previous proposition is extended in an obvious way to the case $\mathrm{X}=\mathbf{P}^{n}$ : if two hypersurfaces $\mathrm{D}_{1}$ and $\mathrm{D}_{2}$, of the same order, have the same tangent cone at every point $\mathrm{P} \notin \operatorname{Supp} \delta_{1} \cup \operatorname{Supp} \delta_{2}$ it follows:

$$
\left(s_{1}-s\right) \delta_{1}^{*} \equiv\left(s_{2}-s\right) \delta_{2}^{*} .
$$
