Topologia. - The Cut Locus of a Finsler Manifold. Nota di Badie T. M. Hassan, presentata ${ }^{(*)}$ dal Socio E. Bompiani.

#### Abstract

Riassunto. - In questa Nota si estendono agli spazi di Finsler completi e/o compattı risultati noti negli spazi di Riemann concernenti la totalità delle geodetiche uscenti da un punto.

## I. Introduction

The study of the cut locus ${ }^{(1)}$ of a Riemannian manifold has led to many interesting results in Riemannian geometry. For example, the proof of the so called "Sphere theorem" due to Rauch [6] depends on estimates of the distance to the cut locus. Moreover, it was realized that much of the topological interest of a manifold lies in its cut locus. A very good account of these results and methods are contained in articles by Klingenberg [3], Kobayashi [4], and Weinstein [7].

The aim of this paper is to extend these methods to the study of the cut locus of a Finsler manifold. As in Riemannian geometry, the exponential map is an important tool in forming the proofs. However, for Finsler manifolds this map is not a $\mathrm{C}^{\infty}$ map, as it is only of class $\mathrm{C}^{1}$ on zero vectors.

## 2. Notational conventions

The following notations will be used throughout this paper.
M : a complete connected Finsler manifold of dimension $n, n \geq 2$, endowed with a general metric $d$. By a general metric we mean one which satisfies all metric properties except the symmetry property.
$\mathrm{T}(\mathrm{M})_{m}$ : the tangent space to M at $m \in \mathrm{M}$.
$\|\mathrm{X}\|:$ norm of the tangent vector $\mathrm{X} \in \mathrm{T}(\mathrm{M})_{m}$.
$\exp$ : the exponential map of $\mathrm{T}(\mathrm{M})_{m}$ onto M .
dexp : the differential of exp.
$\mathrm{S} \quad:\left\{\mathrm{X} \mid\|\mathrm{X}\|=\mathrm{I}, \mathrm{X} \in \mathrm{T}(\mathrm{M})_{m}\right\}$.
$\mathrm{R}^{+}$: the set of positive real numbers.
$\gamma_{\mathrm{X}} \quad:\left\{\left(t, \gamma_{\mathrm{X}}(t)\right) \mid \gamma_{\mathrm{X}}(t)=\exp t \mathrm{X}, t \in[\mathrm{o}, \infty), \mathrm{X} \in \mathrm{S}\right\}$ is a geodesic starting from $m$ with initial vector X and parametrized by arc-length.
$\mathrm{A}_{\mathrm{X}} \quad:\left\{s \mid\right.$ the segment of $\gamma_{\mathrm{X}}$ from $m$ to $\gamma_{\mathrm{X}}(s)$ is minimizing, $\left.s \in \mathrm{R}^{+} \cup\{\infty\}\right\}$. $L\left(\gamma_{x}\right)$ : the length of $\gamma_{x}$.
(*) Nella seduta del 14 aprile 1973.
( I ) For a point $m$ of a manifold M , the cut locus $\mathrm{K}_{m}$ of $m$ in M is the set of all points $p \in \mathrm{M}$ such that there exists a minimal segment from $m$ to $p$ which is not minimizing beyond $p$.

## 3. The cut locus

From the above definition of the set $A_{x}$ it follows that:
(1) $s \in \mathrm{~A}_{\mathrm{x}} \wedge t<s \Rightarrow t \in \mathrm{~A}_{\mathrm{x}}$,
(2) $r \in \mathrm{R}^{+} \wedge\left(s<r \Rightarrow s \in \mathrm{~A}_{\mathrm{X}}\right) \Rightarrow r \in \mathrm{~A}_{\mathrm{X}}$,
(3) $\mathrm{A}_{\mathrm{x}}=(0, r] \quad$ for some $r \in \mathrm{R}^{+} \underline{\vee} \mathrm{A}_{\mathrm{x}}=\mathrm{R}^{+} \cup\{\infty\}$.

If $A_{x}=(0, r]$, then the point $\gamma_{X}(r)$ is called the cut point of $m$ along $\gamma_{x}$. If $A_{x}=R^{+} \cup\{\infty\}$, then no point of $\gamma_{x}$ is a cut point of $m$.

We define a real valued function

$$
c: S \rightarrow \mathrm{R}^{+} \cup\{\infty\}
$$

as

$$
c(\mathrm{X})=\left\{\begin{array}{lll}
r & \text { if } & \mathrm{A}_{\mathrm{X}}=(0, r] \\
\infty & \text { if } & \mathrm{A}_{\mathrm{X}}=\mathrm{R}^{+} \cup\{\infty\}
\end{array}\right.
$$

Set $S_{0}=c^{-1}\left(\mathrm{R}^{+}\right)$. The function

$$
f: \mathrm{S}_{0} \rightarrow \mathrm{~T}(\mathrm{M})_{m}
$$

is defined as $f(\mathrm{X})=c(\mathrm{X}) \mathrm{X}$. The set $f\left(\mathrm{~S}_{0}\right) \subset \mathrm{T}(\mathrm{M})_{m}$ is denoted by $\widetilde{\mathrm{K}}_{m}$.
The function

$$
g: \mathrm{S}_{0} \rightarrow \mathrm{M}
$$

defined as $g=\exp \circ f$ is such that $g(\mathrm{X})$ is a cut point of $m$ along $\gamma_{\mathrm{x}}$. The set $g\left(\mathrm{~S}_{0}\right) \subset M$ is therefore the set of all cut points of $m$ along all geodesics starting from $m$. The set $g\left(\mathrm{~S}_{0}\right)$ is called the cut locus of $m$ in M and is denoted by $\mathrm{K}_{m}$. It is clear that $\exp \widetilde{\mathrm{K}}_{m}=\mathrm{K}_{m}$. The set $\widetilde{\mathrm{K}}_{m}$ is called the cut locus of $m$ in $\mathrm{T}(\mathrm{M})_{m}$ and its points are called cut points of $m$ in $\mathrm{T}(\mathrm{M})_{m}$.

From the fact that geodesics do not minimize arc-length beyond the first conjugate point, it follows immediately that

AsSERTION A. If $p$ is the first conjugate point of $m$ along $\gamma_{X}$, then there is a point of $\mathrm{K}_{m}$ along $\gamma_{\mathrm{X}}$ which is not beyond $p$.

Assertion B. If $\gamma_{\mathrm{x}}$ is a minimal segment from $m$ to $p$ and $p$ is conjugate to $m$ along $\gamma_{X}$, then $p \in \mathrm{~K}_{m}$.

TheOrem 3.1. Let $\left\{\sigma_{i}\right\}$ be a sequence of curves from $m$ to $p$. If $p \notin \mathrm{~K}_{m}$ and limit $\mathrm{L}\left(\sigma_{i}\right)=d(m, p)$, then $\left\{\sigma_{i}\right\}$ converges to the unique minimal segment from $m$ to $p$.

Proof. Since $M$ is complete, then there exists a minimal segment $\gamma_{X}$ from $m$ to $p$. Set $d(m, p)=b, \mathrm{~L}\left(\sigma_{i}\right)=b_{i}$, and let

$$
\sigma_{i}=\left\{\left(t, \exp t \mathrm{X}_{i}\right) \mid t \in\left[\mathrm{o}, b_{i}\right], \mathrm{X}_{i} \in \mathrm{~S}\right\}
$$

For each value of $\delta, 0 \leq \delta<b$, the set of vectors ( $b_{i}-\delta$ ) $\mathrm{X}_{i}$ is contained in some compact subset of $T(M)_{m}$. We may assume, by taking a subsequence if necessary, that

$$
\operatorname{limit}\left(b_{i}-\delta\right) \mathrm{X}_{i}=(b-\delta) \mathrm{Y}, \quad \mathrm{Y} \in \mathrm{~S}
$$

Then,

$$
\gamma_{\mathrm{Y}}=\{(t, \exp t \mathrm{Y}) \mid 0 \leq t \leq b\}
$$

is a minimal segment from $m$ to $p$. It is clear that limit $\sigma_{i}=\gamma_{\mathrm{Y}}$.
If $X=Y$, then $\gamma_{X}=\gamma_{Y}$ and the theorem is proved.
If $\mathrm{X} \neq \mathrm{Y}$, then $\gamma_{\mathrm{X}}(t)$, $0 \leq t \leq b^{\prime}$, is no longer minimizing for every $b^{\prime}$ greater than $b$. This contradicts the assumption $p \notin \mathrm{~K}_{m}$.

Hence the assumption $\mathrm{X} \neq \mathrm{Y}$ is false and the theorem is proved.
Theorem 3.2. If $p \in \mathrm{~K}_{m}$ along a geodesic $\gamma_{\mathrm{X}}$, then at least one of the following statements holds:
(I) $p$ is the first conjugate point of $m$ along $\gamma_{\mathrm{x}}$,
(2) there exist, at least, two minimizing geodesics from $m$ to $p$.

Proof. If $p=\gamma_{x}(r)$, then we choose a monotone decreasing sequence $\left\{a_{k}\right\}, a_{k} \in \mathrm{R}^{+}$, such that limit $a_{k}=r$. Let $b_{k}=d\left(m, \gamma_{\mathrm{x}}\left(a_{k}\right)\right), k \in \mathrm{~N}$. Since M is complete, then $m$ and $\gamma_{\mathrm{x}}\left(a_{k}\right)$ can be joined by a minimal segment, namely

$$
\sigma_{k}=\left\{\left(t, \exp t \mathrm{X}_{k}\right) \mid t \in\left[\mathrm{o}, b_{k}\right], \mathrm{X}_{k} \in \mathrm{~S}\right\}
$$

It is clear that

$$
\mathrm{X} \neq \mathrm{X}_{k} \quad, \quad a_{k}>b_{k} \quad, \quad \text { limit } b_{k}=r
$$

The set of vectors $b_{k} \mathrm{X}_{k}$ is contained in some compact subset of $\mathrm{T}(\mathrm{M})_{m}$. We may assume, by taking a subsequence if necessary, that

$$
\text { limit } b_{k} \mathrm{X}_{k}=r \mathrm{Y} \quad, \quad \mathrm{Y} \in \mathrm{~S}
$$

Then,

$$
\gamma_{\mathrm{Y}}=\{(t, \exp t \mathrm{Y}) \mid t \in[\mathrm{o}, r]\}
$$

is a minimal segment from $m$ to $p$.
Now, we have two cases:
Case I. $\mathrm{X}=\mathrm{Y}$. Then,

$$
\exp b_{k} \mathrm{X}_{k}=\exp a_{k} \mathrm{X}
$$

and

$$
\text { limit } b_{k} \mathrm{X}_{k}=r \mathrm{X}=\operatorname{limit} a_{k} \mathrm{X}
$$

implie that exp is not one-to-one in a neighborhood U of $r \mathrm{X}=r \mathrm{Y}$. Thus dexp is singular there and $p$ is conjugate to $m$ along $\gamma_{X}$.

On the other hand, if $\gamma_{\mathrm{X}}(s), o<s<r$, were conjugate to $m$ along $\gamma_{\mathrm{X}}$, then $\gamma_{\mathrm{X}}$ would not be minimizing beyond $\gamma_{\mathrm{X}}(s)$. Hence $p \notin \mathrm{~K}_{m}$, which is a contradiction. Thus $p$ is the first conjugate point of $m$ along $\gamma_{X}$, and (I) holds.

Case II. $\mathrm{X} \neq \mathrm{Y}$. In this case $\gamma_{\mathrm{x}} \neq \gamma_{\mathrm{Y}}$ and (2) holds.
52. - RENDICONTI 1973, Vol. LIV, fasc. 5.

Theorem 3.3. The mapping $c$ is continuous over S .
Proof. Let $\mathrm{X} \in \mathrm{S}$, and $\left\{\mathrm{X}_{k}\right\}$ be a sequence of points of S such that limit $\mathrm{X}_{k}=\mathrm{X}$. Set $c\left(\mathrm{X}_{k}\right)=a_{k}$. We may assume, by taking a subsequence if necessary, that limit $\left\{a_{k}\right\}$ exists in $\mathrm{R}^{+} \cup\{\infty\}$. Denote this limit by $a$. Then

$$
a=c(\mathrm{X}) \vee a \neq c(\mathrm{X})
$$

We are going to prove that $a \neq c(\mathrm{X})$ is impossible. Hence $a=c(\mathrm{X})$, and $c$ is continuous at $\mathrm{X} \in \mathrm{S}$. Since X is arbitrary, this proves that $c$ is continuous over S .

Let us first assume that $c(\mathrm{X})>a$. Then,

$$
\begin{equation*}
\gamma_{\mathrm{x}}(a) \text { is not conjugate to } m \text { along } \gamma_{\mathrm{x}} \text {, } \tag{I}
\end{equation*}
$$

and

$$
\begin{equation*}
\gamma_{\mathrm{X}}(a) \notin \mathrm{K}_{m} \quad \text { along } \quad \gamma_{\mathrm{X}} . \tag{2}
\end{equation*}
$$

From ( I ) it follows that $\exp$ is non-singular at $a \mathrm{X}$. Hence, there exists a neighborhood U of $a \mathrm{X}$ in $\mathrm{T}(\mathrm{M})_{m}$ on which $\exp$ is a diffeomorphism. As $\left\{a_{k} \mathrm{X}_{k}\right\}$ converges to $a \mathrm{X}$, we may assume, by omitting a finite number of $a_{k} \mathrm{X}_{k}$ if necessary, that all of $a_{k} \mathrm{X}_{k}$ are in U . Since $\exp$ is a diffeomorphism from $U$ onto $\exp U$, it follows that $\gamma_{k}\left(\alpha_{k}\right)$ cannot be conjugate to $m$ along $\gamma_{k}$, where

$$
\boldsymbol{\gamma}_{k}=\left\{\left(t, \exp t \mathrm{X}_{k}\right) \mid t \in\left[0, a_{k}\right]\right\}
$$

Noting that $\gamma_{k}\left(a_{k}\right) \in \mathrm{K}_{m}$ along $\gamma_{k}$, it follows from theorem (2) that there exists another minimizing geodesic $\sigma_{k}$ from $m$ to $\gamma_{k}\left(a_{k}\right)$, namely

$$
\sigma_{k}=\left\{\left(t, \exp t \mathrm{Y}_{k}\right) \mid t \in\left[\mathrm{o}, a_{k}\right], \mathrm{Y}_{k} \in \mathrm{~S}\right\}
$$

We have to note that, for every $k$,

$$
\mathrm{Y}_{k} \neq \mathrm{X}_{k} \quad, \quad \gamma_{k}\left(a_{k}\right)=\sigma_{k}\left(a_{k}\right) \quad, \quad a_{k} \mathrm{Y}_{k} \notin \mathrm{U}
$$

By taking a subsequence if necessary, we may assume that $\left\{\mathrm{Y}_{k}\right\}$ converges to some point $\mathrm{Y} \in \mathrm{S}$. Then $a \mathrm{Y} \notin \mathrm{U}$ and the geodesic

$$
\gamma_{\mathrm{Y}}=\{(t, \exp t \mathrm{Y}) \mid t \in[\mathrm{o}, a]\}
$$

is a minimal segment from $m$ to $\gamma_{X}(a)=\gamma_{Y}(a)$. Hence, both $\gamma_{X}$ and $\gamma_{Y}$ are minimal segments from $m$ to $\gamma_{\mathrm{X}}(a)=\gamma_{\mathrm{V}}(a)$. From (2) and Theorem (I) we can see that this is impossible. Hence $c(\mathrm{X})>a$ is false.

Let us now assume that $c(\mathrm{X})<a$, and let $b$ be a positive number such that $a>c(\mathrm{X})+b$. Set $c(\mathrm{X})+b=a^{\prime}$. As $\left\{a_{k}\right\}$ converges to $a$, we may assume, by omitting a finite number of $a_{k}$ if necessary that $a_{k}>a^{\prime}$, for all $k$.

Since $\gamma_{\mathrm{x}}\left(a^{\prime}\right) \notin \mathrm{K}_{m}$ along $\gamma_{\mathrm{x}}$, it follows from Theorem ( I ) that there exists' a unique minimal segment from $m$ to $\gamma_{\mathrm{X}}\left(a^{\prime}\right)$. This means that there exists a point $X^{\prime} \in S$ such that $X^{\prime} \neq X$ and

$$
\gamma_{\mathrm{X}^{\prime}}=\left\{\left(t, \exp t \mathrm{X}^{\prime}\right) \mid 0 \leq t \leq c(\mathrm{X})+b^{\prime}, b^{\prime}<b\right\}
$$

is a minimal segment from $m$ to $\gamma_{\mathrm{X}}\left(a^{\prime}\right)$. We have to note that

$$
\gamma_{\mathrm{X}}\left(a^{\prime}\right)=\gamma_{\mathrm{X}^{\prime}}\left(c(\mathrm{X})+b^{\prime}\right)
$$

We set $2 r=b-b^{\prime}$. It is clear that

$$
\operatorname{limit} \gamma_{k}\left(a^{\prime}\right)=\gamma_{\mathrm{X}}\left(a^{\prime}\right)
$$

Hence we may assume, by omitting a finite number of $\mathrm{X}_{k}$ if necessary, that there exists a neighborhood U of X such that, for every $k$,

$$
\mathrm{X}_{k} \in \mathrm{U} \quad, \quad d\left(\gamma_{\mathrm{X}}\left(a^{\prime}\right), \gamma_{k}\left(a^{\prime}\right)\right)<r
$$

Let $\alpha$ be a minimal segment from $\gamma_{\mathrm{X}}\left(a^{\prime}\right)$ to $\gamma_{k}\left(a^{\prime}\right)$. For each fixed $k$, consider the curve $\tau$ from $m$ to $\gamma_{k}\left(a^{\prime}\right)$ defined by

$$
\tau= \begin{cases}\exp t \mathrm{X}^{\prime} & 0 \leq t \leq c(\mathrm{X})+b^{\prime} \\ \alpha & \end{cases}
$$

Hence,

$$
\mathrm{L}(\tau)<c(\mathrm{X})+b^{\prime}+r=c(\mathrm{X})+b-r<\mathrm{L}\left(\gamma_{k}\right),
$$

where $L\left(\gamma_{k}\right)$ is the length of $\gamma_{k}$ from $m$ to $\gamma_{k}\left(a^{\prime}\right)$. This means that the geodesic segment of $\gamma_{k}$ from $m$ to $\gamma_{k}\left(a^{\prime}\right)$ is not minimizing. This contradicts the inequality $a_{k}>a^{\prime}$. Hence the assumption $c(\mathrm{X})<a$ is false. This completes the proof.

From the continuity of $c$ it follows immediately that the function $f$ is continuous over $\mathrm{S}_{0}$. Also, from the continuity of $c$ and the exponential map it follows that $g$ is continuous over $\mathrm{S}_{0}$. We also have that

Corollary i. The map

$$
h_{m}: \mathrm{S}_{0} \rightarrow \mathrm{R}^{+}
$$

defined as $h_{m}(\mathrm{X})=d(m, g(\mathrm{X}))$ is continuous over $\mathrm{S}_{0}$.

## 4. The cut locus of a compact manifold

For $X \in S$, let

$$
\mathrm{E}_{\mathrm{x}}=\{\mathrm{Y} \mid \mathrm{Y}=t \mathrm{X}, t \in[\mathrm{o}, c(\mathrm{X}))\}
$$

The set $\mathrm{E}=\cup \mathrm{E}_{\mathrm{X}}$, for all $\mathrm{X} \in \mathrm{S}$, is an open cell in $\mathrm{T}(\mathrm{M})_{m}$ called the interior set in $\mathrm{T}(\mathrm{M})_{m}$. It is clear that $\mathrm{E} \cap \widetilde{\mathrm{K}}_{m}=\varnothing$.

Theorem 4.r. $\exp \mid \mathrm{E}: \mathrm{E} \rightarrow \exp \mathrm{E}$ is a diffeomorphism.
Proof. It is clear that exp is one-to-one onto $\exp$ E. For every $\mathrm{X} \in \mathrm{E}$, $\exp \mathrm{X} \notin \mathrm{K}_{m}$. From assertion (B) it follows that $\exp \mathrm{X}$ is not conjugate to $m$ for every $\mathrm{X} \in \mathrm{E}$. Hence dexp is non-singular at every $\mathrm{X} \in \mathrm{E}$. This completes the proof.

The set $E$ is such that:
(r) exp is a diffeomorphism of E onto an open neighborhood of $m$ in M, namely $\exp \mathrm{E}$.
(2) E is star shaped in the sense that if $\mathrm{Y} \in \mathrm{E}$ then $t \mathrm{Y} \in \mathrm{E}, t \in[\mathrm{o}, \mathrm{r}]$.

Hence E is a normal neighborhood of the origin zero in $\mathrm{T}(\mathrm{M})_{m}$, and $\exp \mathrm{E}$ is a normal neighborhood of $m$ in M , see [2]. In fact E and $\exp \mathrm{E}$ are the largest normal neighborhoods of zero in $\mathrm{T}(\mathrm{M})_{m}$ and of $m$ in M respectively.

Since $\mathrm{E} \cap \widetilde{\mathrm{K}}_{m}=\varnothing$, it follows that $(\exp \mathrm{E}) \cap \mathrm{K}_{m}=\varnothing$. Let $\mathrm{B}=\mathrm{E} \cup \widetilde{\mathrm{K}}_{m}$, then

Theorem 4.2. $\exp \mathrm{B}=\mathrm{M}$.
Proof. For any $p \in \mathrm{M}$, let $d(m, p)=b$ and

$$
\gamma_{\mathrm{X}}=\{(t, \exp t \mathrm{X}) \mid \mathrm{X} \in \mathrm{~S}, \mathrm{o} \leq t \leq b\}
$$

be a minimal segment from $m$ to $p$. Then, $b \leq c(\mathrm{X})$ and therefore $b \mathrm{X} \in \mathrm{B}$. Hence,

$$
p=\exp b \mathrm{X} \in \exp \mathrm{~B}
$$

Hence, $\exp \mathrm{B}=\mathrm{M}$.
From this it follows directly that $\mathrm{M}=(\exp \mathrm{E}) \cup \mathrm{K}_{m}$. Hence $\mathrm{K}_{m}$ is a closed subset of M and $\widetilde{\mathrm{K}}_{m}$ is a closed subset of $\mathrm{T}(\mathrm{M})_{m}$.

Theorem 4.3. The manifold M is compact if, and only if, $\mathrm{S}_{0}=\mathrm{S}$.
Proof. Suppose M is compact, and let $d$ be the diameter of M. If $b>d$, then

$$
\gamma_{\mathrm{X}}=\{(t, \exp \mathrm{tX}) \mid t \in[0, b], \mathrm{X} \in \mathrm{~S}\}
$$

is not a minimal segment from $m$ to $\gamma_{\mathrm{X}}(b)$. Hence, $c(\mathrm{X}) \leq d$. Thus $\mathrm{X} \in \mathrm{S}_{0}$ and $S=S_{0}$.

Conversely, if $\mathrm{S}_{0}=\mathrm{S}$. Then from the continuity of $h_{m}$, it follows that B is closed and bounded in $\mathrm{T}(\mathrm{M})_{m}$, and hence compact. But then $\mathrm{M}=\exp \mathrm{B}$ is compact.

As an immediate consequence of this theorem it follows that.
Corollary i. If every geodesic ray from $m$ has a conjugate point of $m$, then M is compact.

Corollary 2. M is compact if, and only if, the function $f$ is a homeomorphism of $\mathrm{S}_{0}$ onto $\widetilde{\mathrm{K}}_{m}$.
